

Simple Microservice without Visual Studio support

Pre-Requisites: Docker Desktop, .Net 6 SDK

1. Creating a Web Api using dotnet cli
 - a. `dotnet new webapi -o MyMicroservice --no-https -f net6.0`
 - b. `cd MyMicroservice`
 - c. A web Api project will be created with a default controller called WeatherForecastController

2. Run the web api
 - a. `dotnet run`
 - b. Now navigate to the url through the browser.
<http://localhost:portNumber/WeatherForecast>
 - c. Output resembles the following screenshot

```
[{"date": "2021-11-06T12:36:34.5135371-07:00", "temperatureC": 48, "temperatureF": 118, "summary": "Chilly"}, {"date": "2021-11-07T12:36:34.5145705-08:00", "temperatureC": 46, "temperatureF": 114, "summary": "Bracing"}, {"date": "2021-11-08T12:36:34.5145884-08:00", "temperatureC": 47, "temperatureF": 116, "summary": "Mild"}, {"date": "2021-11-09T12:36:34.5145892-08:00", "temperatureC": -14, "temperatureF": 7, "summary": "Hot"}, {"date": "2021-11-10T12:36:34.5145897-08:00", "temperatureC": -3, "temperatureF": 27, "summary": "Freezing"}]
```

- d.
3. Open Docker Desktop to ensure the host is running. Test it by typing the following in the command prompt
 - a. `docker --version`
4. You should now be in the project directory as shown in step 1.
5. To convert your webapi to a microservice, we need to containerize it. To containerize it, Docker is used. To start with creating docker container, a Dockerfile is required. This can be created in multiple ways. As we are doing everything through command-line, let's create the docker file through command-line
 - a. `fsutil file createnew Dockerfile 0`
 - b. `start Dockerfile`
6. Add the following to the docker file in the editor. Here you can choose the editor as notepad

```
FROM mcr.microsoft.com/dotnet/sdk:6.0 AS build
WORKDIR /src
COPY MyMicroservice.csproj .
RUN dotnet restore
COPY . .
RUN dotnet publish -c release -o /app
```

```
FROM mcr.microsoft.com/dotnet/aspnet:6.0
WORKDIR /app
```

```
COPY --from=build /app .  
ENTRYPOINT ["dotnet", "MyMicroservice.dll"]
```

7. Adding a .dockerignore file. This step is optional. It is highlighted here, as when you create a microservice from Visual Studio the .dockerignore file will be available.

- a. `fsutil file createnew .dockerignore 0`
- b. `start .dockerignore`
- c. We shall be ignoring the bin, obj folders completely. To do so, please add the following content to the file

```
Dockerfile  
[b|B]in  
[O|o]bj
```

8. Now, we build the docker container with a tag name, to easily access the image created.

- a. `docker build -t mymicroservice .`

9. To verify that the image was created successfully, use the following command

- a. `docker images`

10. You can run the docker image in the background or interactive mode.

- a. `docker run -it --rm -p 3000:80 --name mymicroservicecontainer mymicroservice`

- i. `-i` : Interactive mode,
- ii. `-t`: A pseudo terminal that connects the user's terminal to container through shell / bash,
- iii. `--rm` : Automatically removes the container when it exits,
- iv. `3000:80`: Bind the container port to the hosts port. While running the container,
- v. `localhost:3000` will be used to execute your container application,
- vi. `--name` : container name

11. Open another command prompt, to view that your container is running

- a. `docker ps`

12. This completes the creation of a microservice using Docker container.
